

AML Entity Screening - SaaS Platform Implementation for NBFC Client

Domain: AML Compliance, PMLA, Sanctions Screening, PEP Identification

Tools Used: Postman, REST API, MS Excel, Process mapping, UAT documentation

Overview:

Implemented AML screening solution for an NBFC client enabling automated entity screening against sanctions lists, PEP databases, and adverse media — replacing manual screening processes.

Problem Statement:

The client's compliance team was manually screening customer names against sanctions and PEP lists using spreadsheets and public databases. This was time-consuming, inconsistent, and created audit trail gaps that posed regulatory risk under PMLA obligations.

My Role:

Business Analyst responsible for client requirement analysis, solution walkthrough, sandbox UAT coordination, and post-production support for AML screening API implementation.

Approach:

Step 1 — Business Requirement Understanding:

Conducted requirement workshops to understand the client's current screening process, regulatory obligations under PMLA, volume of daily screenings required, and expected response time SLA for the screening API.

Step 2 — Solution Walkthrough:

Demonstrated the AML screening platform's capabilities — entity matching logic, sanctions list coverage (OFAC, UN, EU), PEP database, adverse media screening, match scoring, and false positive management workflow.

Step 3 — Functional Gap Analysis:

Identified gaps between client requirements and platform standard configuration — specifically around match threshold sensitivity settings and internal reporting format requirements.

Documented configuration changes required before go-live.

Step 4 — UAT Test Scenario Design:

Designed UAT scenarios covering: true match against sanctioned entity, PEP identification, false positive handling, adverse media match, clean entity screening, and bulk screening performance under load. Obtained formal UAT sign-off from client compliance officer.

Step 5 — Post-Production Support:

Investigated and resolved post go-live false positive alerts — analysed match logic, documented patterns, and coordinated configuration adjustments with internal product team to improve screening accuracy.

Outcome:

- Replaced manual spreadsheet screening with automated real-time API screening
- Created complete audit trail for every screening decision — meeting PMLA compliance requirements
- Reduced false positive investigation time through match threshold optimisation
